CSE 116: Fall 2019

Introduction to Functional Programming

Datatypes and Recursion

Owen Arden UC Santa Cruz

Based on course materials developed by Nadia Polikarpova

What is Haskell?

- · Last week:
 - built-in data types
 - base types, tuples, lists (and strings)
 - writing functions using pattern matching and recursion
- This week:
 - user-defined data types
 - and how to manipulate them using pattern matching and recursion
 - more details about recursion

2

Representing complex data

- We've seen:
 - base types: Bool, Int, Integer, Float
 - some ways to build up types: given types T1, T2
 - functions: T1 -> T2
 - tuples: (T1, T2)
 - lists: [T1]
- Algebraic Data Types: a single, powerful technique for building up types to represent complex data
 - lets you define your own data types
 - subsumes tuples and lists!

,

Product types

• Tuples can do the job but there are two problems...

```
deadlineDate :: (Int, Int, Int)
deadlineDate = (2, 4, 2019)

deadlineTime :: (Int, Int, Int)
deadlineTime = (11, 59, 59)

-- / Deadline date extended by one day
extension :: (Int, Int, Int) -> (Int, Int, Int)
extension = ...
```

• Can you spot them?

1. Verbose and unreadable

```
type Date = (Int, Int, Int)
type Time = (Int, Int, Int)

deadlineDate :: Date
deadlineDate = (2, 4, 2019)

deadlineTime :: Time
deadlineTime = (11, 59, 59)

-- | Deadline date extended by one day
extension :: Date -> Date
extension = ...
```

2. Unsafe

- We want this to fail at compile time!!! extension deadlineTime
- Solution: construct two different datatypes

(

Record Syntax

• Haskell's **record syntax** allows you to *name* the constructor parameters:

Building data types

- Three key ways to build complex types/values:
 - Product types (each-of): a value of T contains a value of T1 and a value of T2 [done]
 - 2. **Sum types** (one-of): a value of T contains a value of T1 or a value of T2
 - 3. Recursive types: a value of T contains a *sub-value* of the same type Ts

8

Example: NanoMD

- Suppose I want to represent a *text document* with simple markup. Each paragraph is either:
 - plain text (String)
 - heading: level and text (Int and String)
 - list: ordered? and items (Bool and [String])
- I want to store all paragraphs in a *list*

Sum Types

- Solution: construct a new type for paragraphs that is a *sum* (*one-of*) the three options!
 - plain text (String)
 - heading: level and text (Int and String)
 - list: ordered? and items (Bool and [String])
- I want to store all paragraphs in a list

10

12

QUIZ

What would GHCi say? * data Paragraph = Text String | Heading Int String | List Bool [String] What would GHCi say to >:t Text "Hey there!" A. Syntax error B. Type error C. Paragraph D. [Paragraph] **E. [String] http://tiny.cc/cse116-para-ind**

.c/cse i io-paia-iii

QUIZ

```
What would GHCi say? *

data Paragraph =
    Text String | Heading Int String | List Bool [String]

What would GHCi say to

>:t Text "Hey there!"

A. Syntax error

B. Type error

C. Paragraph

D. [Paragraph]

E. [String]
```

Constructing datatypes

```
data T =
    C1 T11 .. T1k
  C2 T21 .. T21
  Cn Tn1 .. Tnm
T is the new datatype
C1 .. Cn are the constructors of T
A value of type T is
 • either C1 v1 .. vk with vi :: T1i
 • or C2 v1 .. v1 with vi :: T2i
 • or Cn v1 .. vm with vi :: Tni
```

Constructing datatypes

You can think of a T value as a box:

```
• either a box labeled C1 with values of types T11 .. T1k inside
• or a box labeled C2 with values of types T21 .. T21 inside
• or a box labeled Cn with values of types Tn1 .. Tnm inside
```

```
Apply a constructor = pack some values into a box (and label it)
 • Text "Hey there!"
    • put "Hey there!" in a box labeled Text
 • Heading 1 "Introduction"
    put 1 and "Introduction" in a box labeled Heading
 • Boxes have different labels but same type (Paragraph)
```

14

13

QUIZ

```
data Paragraph =
    Text String | Heading Int String | List Bool [String]
 What would GHCi say to
>:t [Heading 1 "Introduction", Text "Hey there!"]

    A. Syntax error

O B. Type error
O. Paragraph
O. [Paragraph]
E. [String]
```

http://tiny.cc/cse116-adt-ind

QUIZ

```
What is the type of *

data Paragraph =
    Text String | Heading Int String | List Bool [String]

What would GHCi say to

>:t [Heading 1 "Introduction", Text "Hey there!"]

A. Syntax error

B. Type error

C. Paragraph

D. [Paragraph]

E. [String]
```

• .

16

Example: NanoMD

```
data Paragraph =
    Text String | Heading Int String | List Bool [String]
Now!can create a document like so:
doc :: [Paragraph]
doc = [
    Heading 1 "Notes from 130"
    , Text "There are two types of languages:"
    , List True ["purely functional", "purely evil"]
]
```

17

Example: NanoMD

Now I want convert documents in to HTML.

I need to write a function:

```
html :: Paragraph -> String
html p = ??? -- depends on the kind of
paragraph!
```

How to tell what's in the box?

• Look at the label!

Pattern Matching

Pattern matching = looking at the label and extracting values from the box

- we've seen it before
- but now for arbitrary datatypes

```
html :: Paragraph -> String
html (Text str) = ...
    -- It's a plain text! Get string
html (Heading lvl str) = ...
    -- It's a heading! Get level and string
html (List ord items) = ...
    -- It's a list! Get ordered and items
```

19

Dangers of pattern matching (1)

```
html :: Paragraph -> String
html (Text str) = ...
html (List ord items) = ...

What would GHCi say to:
html (Heading 1 "Introduction")
```

Answer: Runtime error (no matching pattern)

20

Dangers of pattern matching (1)

Beware of missing and overlapped patterns

- GHC warns you about overlapped patterns
- GHC warns you about missing patterns when called with -W (use:set -W in GHCi)

Pattern matching expression

We've seen: pattern matching in equations

You can also pattern-match *inside your program* using the case expression:

```
html :: Paragraph -> String
html p =
  case p of
   Text str -> unlines [open "p", str, close "p"]
  Heading lvl str -> ...
  List ord items -> ...
```

22

QUIZ

23

QUIZ

Pattern matching expression: typing

```
The case expression

case e of

pattern1 -> e1

pattern2 -> e2

...

patternN -> eN

has type T if

each e1...eN has type T

e has some type D

each pattern1...patternN is a valid pattern for D

i.e. a variable or a constructor of D applied to other patterns

The expression e is called the match scrutinee
```

QUIZ

```
What is the type of *

let p = Text "Hey there!"

in case p of

Text _ -> 1

Heading _ _ -> 2

List _ _ -> 3

A. Syntax error

B. Type error

C. Paragraph

D. Int

http://tiny.cc/cse116-case2-ind
```

26

25

QUIZ

```
What is the type of *

let p = Text "Hey there!"
in case p of

Text _ -> 1

Heading _ _ -> 2

List _ -> 3

A. Syntax error

B. Type error

C. Paragraph

D. Int

http://tiny.cc/cse116-case2-grp
```

Building data types

- Three key ways to build complex types/values:
 - Product types (each-of): a value of T contains a value of T1 and a value of T2 [done]
 - 2. Sum types (one-of): a value of T contains a value of T1 or a value of T2 [done]
 - 3. Recursive types: a value of T contains a *sub-value* of the same type Ts

28

Recursive types

Let's define natural numbers from scratch:

```
data Nat = ???
```

29

Recursive types

Succ (Succ Zero)

. . .

Succ (Succ (Succ Zero)) -- 3

Functions on recursive types

Principle: Recursive code mirrors recursive data

31

1. Recursive type as a parameter

```
data Nat = Zero -- base constructor
| Succ Nat -- inductive constructor
```

Step 1: add a pattern per constructor

32

1. Recursive type as a parameter

1. Recursive type as a parameter

Step 3: fill in inductive case using a recursive call:

```
toInt :: Nat -> Int
toInt Zero = 0 -- base case
toInt (Succ n) = 1 + toInt n -- inductive case
```

34

QUIZ

What does this evaluate to? *

let foo i = if i <= 0 then Zero else Succ (foo (i - 1)) in foo 2

- A. Syntax error
- O B. Type error
- O C. 2
- O. Succ Zero
- E. Succ (Succ Zero)

http://tiny.cc/cse116-rectype-ind

35

QUIZ

What does this evaluate to? *

let foo i = if i <= 0 then Zero else Succ (foo (i - 1)) in foo 2

- A. Syntax error
- O B. Type error
- O C. 2
- O. Succ Zero
- E. Succ (Succ Zero)

http://tiny.cc/cse116-rectype-grp

2. Recursive type as a result

37

2. Putting the two together

```
data Nat = Zero -- base constructor

Succ Nat -- inductive constructor

add :: Nat -> Nat -> Nat

add Zero m = m -- base case

add (Succ n) m = Succ (add n m) -- inductive case

sub :: Nat -> Nat -> Nat

sub n Zero = n -- base case 1

sub Zero _ = Zero -- base case 2

sub (Succ n) (Succ m) = sub n m -- inductive case
```

38

2. Putting the two together

Lessons learned:

• Recursive code mirrors recursive data
• With multiple arguments of a recursive type,
which one should I recurse on?
• The name of the game is to pick the
right inductive strategy!

sub
Zero _ = Zero -- base case 2

sub (Succ n) (Succ m) = sub n m -- inductive case

Lists

Lists aren't built-in! They are an algebraic data type like any other:

```
length :: List -> Int
length Nil = 0 -- base case
length (Cons _ xs) = 1 + length xs -- inductive case
```

40

Lists

What is the right inductive strategy for appending two lists?

```
append :: List -> List -> List
append ??? ??? = ???
```

41

Lists

What is the right inductive strategy for appending two lists?

```
append :: List -> List -> List
append Nil ys = ys
append ??? ??? = ???
```

Lists

What is the right inductive strategy for appending two lists?

append :: List -> List -> List

append Nil ys = ys

append (Cons x xs) ys = Cons x (append xs ys)

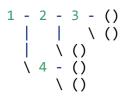

43

Trees

Lists are unary trees with elements stored in the nodes:

```
1 - 2 - 3 - ()
data List = Nil | Cons Int List
```

How do we represent *binary trees* with elements stored in the nodes?

44

QUIZ

What is a Haskell datatype for binary trees with elements stored in the nodes? *

```
1 - 2 - 3 - ()
| | \ \ ()
| \ \ 4 - ()
| \ \ ()

(A) data Tree = Leaf | Node Int Tree

(B) data Tree = Leaf | Node Int Tree

(C) data Tree = Leaf | Node Int Tree Tree

(D) data Tree = Leaf Int | Node Tree Tree

(E) data Tree = Leaf Int | Node Tree Tree

(E) data Tree = Leaf Int | Node Int Tree Tree
```

QUIZ

```
What is a Haskell datatype for binary trees with elements stored in the nodes? \stackrel{\star}{}
```

```
1 - 2 - 3 - ()

| | | \ ()

| \ \ ()

\ \ 4 - ()

\ \ ()

(A) data Tree = Leaf | Node Int Tree

(B) data Tree = Leaf | Node Int Tree Tree

(C) data Tree = Leaf | Node Int Tree Tree

(D) data Tree = Leaf Int | Node Tree Tree

(E) data Tree = Leaf Int | Node Int Tree Tree
```

46

Trees

47

Functions on trees

```
depth :: Tree -> Int
depth Leaf = 0
depth (Node _ 1 r) = 1 + max (depth 1) (depth r)
```

QUIZ

What is a Haskell datatype for binary trees with elements stored in the leaves? $\!\!\!\!\!\!\!^\star$

49

QUIZ

What is a Haskell datatype for binary trees with elements stored in the leaves? $\mbox{\ensuremath{^\star}}$

50

Binary trees

Example: Calculator

I want to implement an arithmetic calculator to evaluate expressions like:

```
• 4.0 + 2.9
• 3.78 - 5.92
• (4.0 + 2.9) * (3.78 - 5.92)
```

What is a Haskell datatype to represent these expressions?

```
data Expr = ???
```

52

Example: Calculator

How do we write a function to evaluate an expression?

```
eval :: Expr -> Float
```

53

Example: Calculator

How do we write a function to evaluate an expression?

```
eval :: Expr -> Float
eval (Num f) = f
```

Example: Calculator

55

Example: Calculator

How do we write a function to evaluate an expression?

```
eval :: Expr -> Float
eval (Num f) = f
eval (Add e1 e2) = eval e1 + eval e2
eval (Sub e1 e2) = eval e1 - eval e2
```

56

Example: Calculator

How do we write a function to evaluate an expression?

```
eval :: Expr -> Float
eval (Num f) = f
eval (Add e1 e2) = eval e1 + eval e2
eval (Sub e1 e2) = eval e1 - eval e2
eval (Mul e1 e2) = eval e1 * eval e2
```

Recursion is...

Building solutions for *big problems* from solutions for *sub-problems*

- Base case: what is the *simplest version* of this problem and how do I solve it?
- Inductive strategy: how do I break down this problem into sub-problems?
- Inductive case: how do I solve the problem *given* the solutions for subproblems?

58

Why use Recursion?

- 1. Often far simpler and cleaner than loops
 - But not always...
- 2. Structure often forced by recursive data
- 3. Forces you to factor code into reusable units (recursive functions)

59

Why **not** use Recursion?

- 1.Slow
- 2.Can cause stack overflow

Example: factorial

```
fac :: Int -> Int
fac n
  n <= 1 = 1
  otherwise = n * fac (n - 1)
<fac 4>
 ==> <4 * <fac 3>>
                            -- recursively call `fact 3`
 ==> <4 * <3 * <fac 2>>>
                          -- recursively call `fact 2`
 ==> <4 * <3 * <2 * <fac 1>>>> -- recursively call `fact 1`
 ==> <4 * <3 * <2 * 1>>> -- multiply 2 to result
 ==> <4 * <3 * 2>>
                            -- multiply 3 to result
 ==> <4 * 6>
                            -- multiply 4 to result
  ==> 24
```

61

Example: factorial

Each function call <> allocates a frame on the call stack

- expensive
- the stack has a finite size

Can we do recursion without allocating stack frames?

62

Tail recursion

Recursive call is the *top-most* sub-expression in the function body

- i.e. no computations allowed on recursively returned value
- i.e. value returned by the recursive call == value returned by function

QUIZ

Is this function tail recursive? *

http://tiny.cc/cse116-tail-ind

64

QUIZ

(B) No

Is this function tail recursive? *

http://tiny.cc/cse116-tail-grp

Tail recursive factorial

Let's write a tail-recursive factorial!

Tail recursive factorial

Each recursive call **directly** returns the result

- without further computation
- no need to remember what to do next!
- no need to store the "empty" stack frames!

67

Tail recursive factorial

Tail recursive factorial

- Tail recursive calls can be optimized as a loop
 - no stack frames needed!
- Part of the language specification of most functional languages
 - compiler guarantees to optimize tail calls
